2
3 DEPTH SENSITIVE MECHANICAL ACOUSTIC SIGNAL GENERATING DEVICE

4
5 STATEMENT OF GOVERNMENT INTEREST

6 The invention described herein may be manufactured and used
7 by or for the Government of the United States of America for
8 governmental purposes without the payment of any royalties
9 thereon or therefore.

10
11 BACKGROUND OF THE INVENTION

12 (1) Field of the Invention

13 The present invention relates generally to acoustic signal
14 generating devices, and more particularly to a mechanical device
15 capable of generating an acoustic signal at a specific depth.

16 (2) Description of the Prior Art

17 Acoustic signals in active sonobuoys are produced by an
18 array of active transducers that are driven electronically by
19 means of a signal generator, a power source and an electric
20 driver stage. The power source provides the necessary power to
21 operate the signal generator and the electronic driver.
22 Typically, the power source is a battery. The signal generator
23 produces a specified signal and passes the signal to the driver
24 stage where it is amplified so as to drive the active transducer

1 array. The array produces the acoustic signal which is
2 propagated through the water. Such electronically driven
3 generators are complex, costly and have suffered from being
4 unreliable. A simplified mechanically driven generator can
5 reduce cost and can be made more reliable.

6 However, prior art mechanical sound generators are also
7 typically complex, often relying on compressed gas or motors to
8 actuate a striker against a plate. For example, U.S. Patent No.
9 3,433,202 to Sharp et al. discloses an impact energized sound
10 source which uses compressed gas to propel a striker through an
11 evacuated guide tube and against a radiating plate. U.S. Patent
12 No. 3,137,834 to Bielecki et al. discloses an underwater
13 mechanical sound generator resulting from the movement of motor
14 driven pistons within the device. U.S. Patent No. 3,053,220 to
15 Sawyer discloses an underwater impact sound source having a dual
16 spring-loaded impact rod. A free floating striker is attached to
17 the rod while the springs and impact rod are each are mounted on
18 telescoping tubes, all adding to the devices complexity. Also,
19 the Sawyer device makes no provision for actuating the device at
20 a specific depth. Other, similarly complex, and/or non-depth
21 sensitive devices are disclosed by Abrahamsen et al. and Donsky
22 in U.S. Patent Nos. 3,229,404 and 5,233,570, respectively. In
23 abandoned application Ser. No. 07/904,626, current inventor
24 Sullivan disclosed a mechanical sound generator including a

1 pressure sensitive piston which acted against two rods fixed end
2 to end. The separation of the rods by the piston allowed a
3 spring activated piston to strike a ledge, causing the acoustic
4 signal. As the rods were fixed end to end, there was a distinct
5 possibility that jarring of the device would cause premature
6 actuation, especially as the device may be dropped into the water
7 from a considerable distance. Also, the end to end configuration
8 could lead to assembly problems when trying to align the rod
9 ends.

10 11 SUMMARY OF THE INVENTION

12 Accordingly, it is an object of the present invention to
13 provide a simple mechanical device which can generate an acoustic
14 signal at a specified depth.

15 Another object of the present invention is to provide a
16 device which is not susceptible to premature actuation when
17 jarred.

18 Still another object of the present invention is to provide
19 a device which can be easily assembled.

20 Other objects and advantages of the present invention will
21 become more obvious hereinafter in the specification and
22 drawings.

23 In accordance with the present invention, a depth sensitive,
24 mechanical, acoustic signal generating device is provided. The

1 device consists of a shear plug which prevents the movement of a
2 spring biased piston. The plug is located in an exterior wall of
3 the device housing so as to be subjected to increasing
4 differential pressure as the depth of the device beneath the
5 water surface increases. At a known pressure differential,
6 corresponding to a specified depth, the shear plug fails,
7 allowing for the actuation of the piston. The spring biased
8 piston strikes against a ledge in the device, creating the
9 acoustic signal.

10 The device thus described is a simple mechanical device
11 having only four major components, i.e., a housing, a piston, a
12 shear plug and a biasing means. The shear plug is designed to
13 fail at a specific pressure, corresponding to a specified water
14 depth. The simplicity of the device allows for quick assembly,
15 and, once assembled, the device is not subject to premature
16 actuation.

17 18 BRIEF DESCRIPTION OF THE DRAWINGS

19 A more complete understanding of the invention and many of
20 the attendant advantages thereto will be readily appreciated as
21 the same becomes better understood by reference to the following
22 detailed description when considered in conjunction with the
23 accompanying drawings wherein like reference numerals refer to
24 like parts and wherein:

1 FIG. 1 is a cross sectional view of a preferred embodiment
2 of the present invention; and

3 FIG. 2 is a cross sectional view of a second embodiment of
4 the present invention.

5
6 DESCRIPTION OF THE PREFERRED EMBODIMENT

7 Referring now to FIG. 1, there is shown a side sectional
8 view of the present invention. The device 10 consists of a
9 housing 12, preferably cylindrical, having a piston 14 and a rod
10 16 mounted within cylindrical chamber 18 of housing 12. One or
11 more o-rings 14a provide a seal between piston 14 and chamber
12 walls 18a. Rod 16 extends from the piston 14, through spring
13 bore 20 and rod bore 22 and is seated against shear plug 24 which
14 seals rod bore 22 at the base 12a of the housing 12. Shear plug
15 24 is designed to fail at a specified force, or load. As shown
16 in FIG. 1, shear plug 24 is bonded within rod bore 22. The shear
17 strength of the adhesive bond determines the failure load. A
18 spring 26 is stretched and attached between the piston 14 and the
19 housing 12 at spring bore 20, exerting a force against piston 14
20 to pull piston 14 toward shelf 28 of housing 12. When the device
21 10 is lowered in the water, water pressure against piston 14
22 results in rod 16 exerting a force against shear plug 24. The
23 force resulting from the water pressure over the piston 14 is
24 greater than the force exerted by the water pressure acting on

1 shear plug 24 due to the larger area of the piston 14. At a
2 predetermined depth, the force differential will cause the shear
3 plug 24 to fail allowing rod 16 to pass through the bore 20, now
4 left open by the failed shear plug 24. Spring 26 pulls piston 14
5 against shelf 28 with sufficient force to create an acoustic
6 signal. It is noted that rod 16 fits snugly, but movably within
7 bore 20 such that the piston 14 strikes shelf 28 evenly. Housing
8 12 can be fabricated from solid cylindrical stock with shelf 28
9 and bores 20 and 22 cut into housing 12. To assemble the device
10 10, the spring 26 is first attached at the base 20a of spring
11 bore 20. Shear plug 24 is then inserted and fixed in rod bore
12 22. Next, rod 16 is placed within rod bore 22 and spring 26 is
13 stretched and attached to rod 16 at its upper end 16a. Piston 14
14 is then attached to end 16a of rod 16.

15 FIG. 2 shows a side sectional view of a second embodiment of
16 device 10. As in the embodiment of FIG. 1, piston 14 and rod 16
17 are mounted within cylindrical chamber 18 of housing 12. Rod 16
18 extends into rod bore 22 to help maintain the alignment of piston
19 14 within chamber 18. Shear plug 24 is shown incorporated into
20 cover 30. Shear plug 24 is placed over cover bore 30a and seals
21 cover bore 30a. The seal may be accomplished by o-rings (not
22 shown), using the force of spring 26 to hold plug 24 against the
23 o-rings. Shear plug 24 may also be bonded within depression 30b
24 of cover 30. In the embodiment of FIG. 2, shear plug 24 is

1 designed to fail by shearing at a specified force. Hook 32 is
2 attached to piston 14. Hook 32 engages eye 34 attached to shear
3 plug 24, with spring 26 compressively engaged between cover 30
4 and piston 14. To assemble device 10 of the embodiment of FIG.
5 2, shear plug 24, with attached eye 34, is first sealed into
6 cover 30. Spring 26 is then placed over hook 32, spring 26 is
7 compressed and hook 32 is attached to eye 34. The cover
8 assembly, consisting of cover 30, shear plug 24, hook 32, eye 34,
9 spring 26, piston 14 and rod 16, is then sealingly attached to
10 housing 12, making sure rod 16 and piston 14 are aligned within
11 rod bore 22 and chamber 18. Cover 30 may be sealed to housing 12
12 by bonding, o-rings (not shown), bolts (not shown), threads (not
13 shown), or other well known means. When the pressure against
14 shear plug 24 due to the water depth increases beyond the failure
15 point of shear plug 24, shear plug 24 fails, releasing spring 26,
16 which forces piston 14 against shelf 28 to create the acoustic
17 signal.

18 The shear plug and piston mechanism of the present invention
19 provides a simple means for mechanically generating an acoustic
20 signal. The components are easily assembled, without the
21 requirement of matching the ends of relatively narrow rods. The
22 device is rugged, with little chance of prematurely activating
23 due to rough handling.

1 Although the present invention has been described relative
2 to specific embodiments thereof, it is not so limited. As
3 described for the embodiments of FIGS. 1 and 2, the shear plug
4 can be made to fail at a specified depth by any one of many well
5 known methods. The embodiment of FIG. 1 is bonded in place with
6 the bonding having a known shear strength. In the embodiment of
7 FIG. 2, the shear plug itself is designed with a known shear
8 strength. The shear plug may also be fabricated directly into
9 the housing, or into the cover for the embodiment of FIG. 2, by
10 notching the housing or cover in such a manner as to cause
11 failure at a certain pressure. In addition, the housing can also
12 be cast with the shelf and bores already in place rather than
13 being bored. The device may also be constructed with other than
14 the spring biasing means of FIGS. 1 and 2, e.g., rubber bands or
15 other elastomeric compounds may be used.

16 Thus, it will be understood that many additional changes in
17 the details, materials, steps and arrangement of parts, which
18 have been herein described and illustrated in order to explain
19 the nature of the invention, may be made by those skilled in the
20 art within the principle and scope of the invention.

1 Attorney Docket No. 79461

2

3 DEPTH SENSITIVE MECHANICAL ACOUSTIC SIGNAL GENERATING DEVICE

4

5 ABSTRACT OF THE DISCLOSURE

6 A simple, mechanical device is provided which produces an
7 acoustic signal at a specified depth. The device consists of a
8 shear plug in an exterior wall of the device housing which
9 prevents the movement of a spring biased piston. The plug is
10 subjected to increasing differential pressure between the
11 exterior and interior of the housing as the depth of the device
12 beneath the water surface increases. At a known pressure
13 differential, corresponding to a specified depth, the shear plug
14 fails, allowing for the actuation of the piston. The spring
15 biased piston strikes against a ledge in the device, creating the
16 acoustic signal.
